

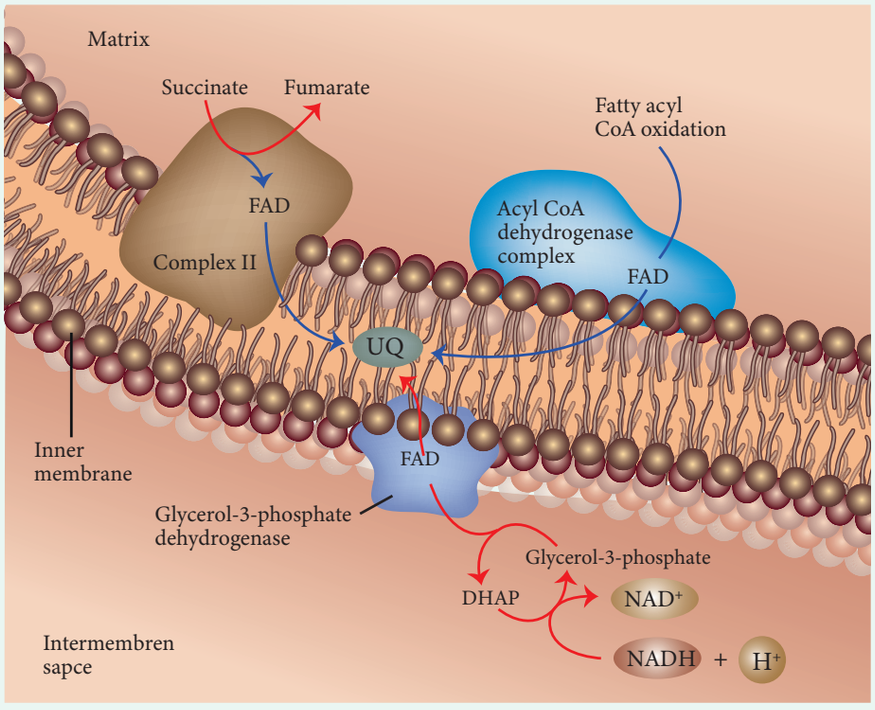

Figure 8.6. Succinate dehydrogenase complex

Cytochrome reductase : Electrons from reduced ubiquinone (UQH_2) are passed to cytochrome c via Complex III. Cytochromes are proteins with heme prosthetic group. All cytochromes have the tendency to act as electron carriers. Once the electron is accepted, the iron atom of heme group changes from Fe^{3+} to Fe^{2+} state. The pathways of electrons transfer from UQH_2 to cytochrome c is quite complex. As represented in Fig.8.7, UQH_2 is oxidized to UQ in a multistep process. One electron is transferred to cytochrome c via Rieske Fe-S protein / cyt c1 and the second electron is transferred to Cyt b.
