3. The serially diluted sample is spread on the nutrient agar plates
4. The plates are incubated and the agar plate having 300 to 400 colonies are observed for antibiotic producing activity
5. The ability of a colony to exhibit antibiotic activity is indicated by the presence of a zone of growth inhibition surrounding the colony
6. The technique is improved by using test organism
7. The antibiotic produced by the organisms in the soil may inhibit the growth of test organism
8. The formation of inhibitory zones around certain colonies indicates their antibiotic sensitivity
9. The diameter of the zones of inhibition is measured in millimeters. Crowded plate technique is depicted in the diagram (Figure 6.3).

Enrichment isolation

The process of enrichment provides a suitable condition to support the growth of microorganisms. It allows the growth of the specific microbe while inhibiting the other non-target microbe. The growth of target microorganisms is enriched
